Terminology and TLAs

We will explore how APL can interact with and use some of these technologies:

OLE - Object Linking and Embedding	sharing properties and methods of applications by combining and exposing objects within a standard framework (eg. document)
& OLE Automation	(<i>Wikipedia:</i>) the formal interprocess communication mechanism based on COM. It provides an infrastructure whereby applications can access and manipulate (i.e. set properties of or call methods on) shared automation objects that are exported by other applications. It supercedes DDE. The OLE Automation controller is the "client" and the application exporting the automation objects is the "server".
COM - Component Object Model DCOM - Distributed COM	(MS 2000 Automation Help:) an industry-standard technology that applications use to expose their objects, methods, and properties to development tools, macro languages, and other applications. (DCOM = COM extended for network apps.)
	(<i>Wikipedia:</i>)often used in the software development world as an umbrella term that encompasses the OLE, OLE Automation, ActiveX, COM+ and DCOM technologies.
OLE Server	a usually invisible application which supports the main interface (client)
	(<i>MFC</i> :) an Automation server is an application (a type of COM server) that exposes its functionality through COM interfaces to other applications, called Automation clients. The exposure enables Automation clients to automate certain functions by directly accessing objects and using the services they provide.
	(<i>Dyalog Help:</i>) The OLEServer object allows you to export an APL namespace so that its functions and variables become directly accessible to an OLE Automation client application such as Microsoft Visual Basic or Microsoft Excel.
OLE Client	the application interface or application which controls or calls upon the OLE Server.
ActiveX Control	a usually visible object which user interacts with; may be embedded in another application.
	(Wikipedia:) a Microsoft term that is used to denote reusable software components that are based on Microsoft Component Object Model (COM). ActiveX controls provide encapsulated reusable functionality to programs and they are typically but not always visual in nature.
	(<i>Microsoft:</i>) an ActiveX control is implemented as an in-process server (typically a small object) that can be used in any OLE container.
Object Oriented	numerous meanings, but generally: a modular approach, using reusable units (called object, class , control, etc.) with common design, including properties , methods , and events ; (nouns, verbs, things that happen?)
	(APL+Win:) an instance of any class is an object.
	consider an everyday example: book
ADO - ActiveX Data Objects	MS specification for interfacing to databases, using ActiveX/COM structure and methodology
DAO - Data Access Objects	older MS specification for database access, similar to ADO; see: C:\Program Files\Common Files\Microsoft Shared\DAO\DAO35.hlp
ODBC - Open Data Base Connectivity	older MS specification for interfacing to databases via SQL queries

Dyalog APL - Terminology

OLEClient	object that enables your APL application to interact with non-APL objects (eg. Excel)
OLEServer	created by converting an APL Namespace to an object (APL workspace or .dll), which is then referred to by any non-APL application (eg. Excel); requires dyalog.dll to run
OCXClass	object used to access non-APL-derived ActiveX controls
	(OCX being one of several names associated with this class of objects)
ActiveXControl	stand-alone object created by APL, but accessed from non-APL applications; requires dyalog.dll to run - based on a Dyalog Namespace object
ActiveXContainer	"read-only"; used to represent the application that is hosting an ActiveXControl object, and provides access to its ambient properties (eg. Font, colour) (see: OLEQueryInterface Method, etc.)
GUI Memory	use '.' (root object), and 🗆wc, 🗆wn, 🗆ws, 🗆wg to identify and explore
GUID or CLSID	Globally Unique IDentifier or CLaSs IDentifier - Windows handle

Let's take a glimpse of some of these things,

Client? Server? and other Options

Noting all of the above, what do you really want to do? It boils down to a few possibilities:

- 1) **In APL** (development session), or an APL-GUI (runtime) application you **write** data to Excel, etc., eg. format and print; further processing, eg. charts), or you **read** data into your APL environment from Excel.
- 2) **In Excel** you call upon APL functions to perform calculations, run an existing APL utility, read an APL-driven database etc. and return results, or you send Excel data to an APL system and have it processed there.
- 3) **Other OLE Options** eg. create ActiveX controls using APL; use non-APL ActiveX objects from within APL; use ADO for database access; etc.

Excel - Components and Overview

Excel's Object-Oriented Structure

In very brief terms, the Excel spreadsheet is a hierarchical collection of objects; objects have properties; most have methods; and when we interact with these objects - events take place. This is the model we must work with to program such applications from any point of view, including APL.

Excel Help provides a good visual display of these objects, and an in-depth resource for understanding how to use these: for starters, try:

"Contents and Index" > "Microsoft Excel Visual Basic Reference" > "Microsoft Excel Object Model" (it's Microsoft, so your version may differ!)

This diagram displays the hierarchical relationships between objects. Click on any of these to explore the details further down the branches of the tree to expand further levels. Notice the top-level object is called "Application".

Key Excel Components and Concepts

Obvious

Menu	Windows standard
Toolbars	one or more; contain tool buttons, combos, etc.; user may modify
Formula Bar	input area
Name Box	give a name to a cell or range
Workbooks	collection object containing individual Workbooks, ie. opened *.xls files, each one being a Workbook object
Worksheets	(or Sheets) collection object; tabs at bottom-left; add, delete, move
Rows/Columns	A1:Z99 designation; some maximum values; note Rows numeric, Columns alpha; drag/drop heading areas to resize; Ctrl-down-arrow etc.
Cells	contain values or formulas; many properties to consider: datatype, format, font, behaviour, alignment (text left, num right), etc.

Not so obvious

Selection	Method and Property; drag/drop to select one or more contiguous cells, or whole Rows/Columns/Worksheets; highlight and modify content or format
Collection	special Excel object used to contain other objects, eg. Workbook > Worksheets; Item and Count properties are useful; special syntax needed in APL
Item	Property; collection object unit; demo: select cells, hit Enter key repeatedly
Count	Property; collection object unit count
Range	ambiguous term: span of cells (Property) vs. Range Object; defines a collection of cells (like an array), either contiguous or non (may even span Worksheets)
PrintOut	and other Methods; eg. print an object; Open, Close, Quit, Select, Activate, etc.
numerous sub- objects	various commonly-used objects and nomenclature such as UsedRange, ThisWorkbook, ActiveSheet, ActiveChart, etc.
VBA/Macros; GUI elements	GUI objects and code stored as part of the spreadsheet; macro recording facility; built-in edit and debug environment

Now, let's go back to APL. First, we need to spend 5 minutes on:

APL GUI Programming - 101 (very lite)

In all APLs, object programming is accomplished with some handy □-functions

Dyalog	Examples
□ w C = create	'F' DWC 'Form'
□ws = set	'F' DWG 'PropList'
□WG = get	'F' DWG 'Size' 'Posn'
□ wn = names	'F' □WS 'Caption' 'Hello World'
□DQ = wait	'F' □WS 'BCol' 255 0 0
□ NQ = invoke	'F.B1' □WC 'Button' 'OK'('Event' 'Select' '호□EX''F''')
	'F.ED1'
	□WN 'F'
	□DQ'F'
and	F.Caption←'Goodbye World'

In similar fashion, we can take this methodology, and apply it to the Excel object, or other COM objects.

Exploring the Excel Object (from APL)

From APL, to use an OLE object as a server, we create an OLEClient object, which is implemented like a "namespace" in Dyalog APL, and we associate a particular server object with it, eg.:

```
□WX ← 1 A see: "New External Object Behaviour" below

'XL' □wc 'OLEClient' 'Excel.Application'
```

This creates an OLEClient object which will interact with an OLE Server, with the ClassName property as specified from our list of OLEServers, ie. from the Root Object property which examines the Windows Registry.

'xl' becomes a namespace object which we can explore or query and use. Dyalog provides system commands to enable us to explore a namespace's objects:

```
) CS XL
) methods
) events
) props
A list properties

Version
LibraryPath
Columns.Count
```

The above can also be accomplished via $\square \mathbf{w}$ syntax from the root level:

Dyalog also allows the use of direct object/property naming via "." syntax, eg.

```
XL.PropList
XL.Version
XL.Visible
XL.Visible+1
XL.visible+0
```

L. visible←0 A suddenly, case matters! (and AutoComplete helps a lot)

XL.Rows.Count

Interesting diversion...

```
XL.Speech.Speak 'Are we having fun now? Or what?'
XL.Speech.Speak 'hey dood, this is sew, koole'
XL.Speech.Speak 'hasta la vista, mi amor'
XL.Speech.Speak 'wut, in, hayl, yoo, thank, yer, dooon, bo ah?'
```

Also, Dyalog provides the "Workspace Explorer" tool to browse such objects.

Want to find out what any of these properties, methods or events really means? For starters, try searching for the particular term in the Excel/VBA Help feature.

Some Key Points

- Dyalog implements GUI memory and OLE objects using the namespace concept, hence)OBS or □NL lists these;)CS or the object.object syntax allows us to explore, etc.;)ERASE or □EX erases the object; assignment ← is used to set properties; □NQ or object.object syntax is used to invoke methods; even the each operator can be put to use for implicit looping, etc.
- upper/lower case-sensitivity varies when addressing properties, methods and events (according to the syntax used?)
- Dyalog AutoComplete displays object Properties; useful to explore objects to some extent
- Incorrect usage often returns a useful response, eg. Methods are indicated by APL del symbol ▼ when invoked but missing an argument, eg. XL.Columns.AutoComplete or in fact an "Exception Error" may appear in a separate "Status" form, eg. try XL.Workbooks.Open with an invalid path/filename.
- Visibility is Excel visible in the task bar? Processes in Task Manager? etc.; set the Visible property
- Is Excel already running?
 - see: http://apldn.apl2000.com/Discussion+Groups/APL+Win+Interpreter/APL+Interpreter+General/797.aspx.htm
- Which 'Excel.Application' server object name to use?
 see: "How to run multiple versions of Excel on the same computer" http://support.microsoft.com/kb/214388
- □wx and Version 11.0 External Object Behaviour see: Language Help > □wx > External Object Behaviour
- 3 DNQ invokes a method in an OLE Control. The (shy) result of DNQ is the result produced by the method.
- Collection Objects can be confusing, require special syntax, see below

Collection Objects

Consider these definitions from the Excel-Help:

Workbook Object - The Workbook object is a member of the Workbooks collection.

Workbooks Collection Object - A collection of all the Workbook objects that are currently open in the Microsoft Excel application.

Workbooks Property - Returns a Workbooks collection that represents all the open workbooks. Read-only.

Worksheet Object - Represents a worksheet. The Worksheet object is a member of the Worksheets collection. The Worksheets collection contains all the Worksheet objects in a workbook.

Worksheets Collection Object - A collection of all the Worksheet objects in the specified or active workbook. Each Worksheet object represents a worksheet.

See also: ActiveWorkbook; ThisWorkbook; Sheets; ActiveSheet; etc.

In other words, the many objects, levels and similar terms can be confusing. The main points are that collection objects have a special purpose and syntax, and we may refer to the objects they contain by using the **Item** property or equivalent reference via indexing. Compare the following:

First, look for this file or equivalent: 'c:\Program Files\Microsoft Office\Clibrary\common.xls', then:

Collection objects are typically a part of the hierarchy or path to get to the underlying information in the spreadsheet. The key Collection Objects include: Workbooks, Sheets (Worksheets), Rows, Columns, Range.

Use ...Item N or indexing (via [N]) to select a Collection Object Item

APL in Control

First, look for this file or equivalent: 'c:\Program Files\Microsoft Office\Office\Library\common.xls', then find a second .xls file on your system to open, then work through these examples:

```
'XL' | WC 'OLEClient' 'Excel.Application'
       XL.Workbooks.Open 'c:\... \common.xls'
       XL.Workbooks.Open 'c:\... \secondspreadsheet.xls'
       XL.Workbooks.Count
       XL.Workbooks.PropList
       XL.Workbooks.Item
       XL.Workbooks.Item 1
       (XL.Workbooks.Item 1) □wg 'PropList'
       (XL.Workbooks.Item 1).PropList
       WB1+XL.Workbooks.Item 1 ♦ WB2+XL.Workbooks.Item 2
       WB1.Name ♦ WB2.Name
       DISPLAY (WB1.Sheets.Item 'tWB1.Sheets.Count).Name
       WB1.Sheets[1].PropList
       WB1.Sheets[1].Cells
       WB1.Sheets[1].Cells.Range
       (WB1.Sheets[1].Cells.Range 'A1' 'D5').PropList
       (WB1.Sheets[1].Cells.Range 'A1' 'D5').Value2
       (WB1.Sheets[1].Range 'A1' 'D5').Value2
       M+WB1.Sheets[1].UsedRange.Value2
       □NULLE M
       WB1.Sheets[1].UsedRange.Cells.Count
       WB1.Sheets[1].UsedRange.Rows.Count
       WB1.Sheets[1].UsedRange.Rows[4].Value2
       WB1.Sheets[1].UsedRange.Columns[4].Value2
To Create a new Workbook (spreadsheet) and Write to it (the basics):
       WB3+XL.Workbooks.Add 1
       (WB3.Sheets[1].Range'A1' 'E5').Value2\leftarrow5 5\rho125
       XL.Visible+1
       (WB3.Sheets[1].Range'A1' 'E5').Value2←125
       WB3.SaveAs 'APL2XLdemo1.xls'
       WB3.Path
       WB3.Close 1
```

Datatypes, Formatting, and Related Issues

COM objects such as Excel typically have data represented by more datatypes than those available in APL. Excel datatypes for example include: Boolean, Date/Time, Double, Error, Integer, Long, String, Currency, Variant.

When transferring data back and forth between APL and Excel therefore, we may need to pay attention to the datatype of our data to make sure it is both stored and represented (displayed) correctly.

- APL provides Inull (displayed as [Null]) which is used to represent null values which COM methods often return. Other data conversions for data transferred between systems are automatic
- Value vs. Value2? (from Excel-Help)

"The only difference between (the Value2) property and the Value property is that the Value2 property doesn't use the Currency and Date data types. You can return values formatted with these data types as floating-point numbers by using the Double data type." (ie. use Value2)

```
In some cases?? ...Value seems to require a null argument, eg.

(WB3.Sheets[1].Range'A1' 'E5').Value θ
```

• IS Functions (from Excel-Help) - use these to determine particular characteristics of cells, eg.

```
XL.ISNUMBER XL.Workbooks[1].Sheets[1].UsedRange
```

This returns a 2-cell result with a boolean array in cell-1, indicating cells with numeric values (presumably of any of the numeric datatypes?).

• Information Functions (from Excel-Help) - further IS functions to return characteristics of cell contents.

Note that not all of the above IS_ functions are available - see XL.MethodList - ie. some Methods are "exposed", others are not (?); and the list seems to grow as these are used (??).

• Formula vs. Value?

Enter some formulae on a spreadsheet, then compare ...Range.Value2 vs. ...Range.Formula

• Create your own worksheet function?

see: http://office.microsoft.com/en-us/assistance/HA010548461033.aspx

```
eg. Function HYPOT (D1, D2) 
 HYPOT = (((D1 \land 2) + (D2 \land 2)) \land 0.5)
 End Function
```

...says you need to "...copy the function into a workbook used as a function library and compile that workbook as an add in program..."

- APL+Win offers root-object-level query & set functionality for data type and value (see the VT_VV workspace).
- Under-filling cells results in "#N/A", eg.

```
(XL.Workbooks[1].Sheets[1].Range'D15' 'F17').Value2+2 2ρ14
```

Dates

Dates are stored in Excel as a day-count number (days since 1900-01-01) but typically represented (displayed) in other ways, such as '16-Oct-06'. Make sure your date information in Excel is numeric and not a character string that looks like a date. There are several display options, see Format > Cells > Number > Date in the Menu, or In in *Excel-Help*, see: "Available Number Formats" > "Display numbers as dates or times" > "Custom date and time codes".

When calculating day-count values, note that Excel incorrectly counts 1900 as a leap year, hence dates are offset by 1 between APL and Excel (see DateToIDN Method in Dyalog GUI Help > IDN definition).

Some examples: (open a spreadsheet... enter some dates, numerics and text if not already present...)

```
WB1+XL.Workbooks.Item 1
    RNG1+WB1.Sheets[1].Range'A1' 'A7'
                                                 A choose any appropriate range with dates
   RNG1.NumberFormat
   RNG1.NumberFormat+'yyyy/mm/dd'
                                                 A and have a look at the Excel result
   RNG1.NumberFormat+'###.####'
   RNG1.NumberFormat+'$###.00'
    ) COPY C:\...\WS\UTIL SM TS TS SM DISP
    TODAY←SM TS 3↑□TS
    WB2+XL.Workbooks.Add 1
                                    A create a new Workbook, write some numbers and dates
   RNG2+WB2.Sheets[1].Range'B3' 'F7'
   RNG2.Value2 \leftarrow (TODAY+0,14),5 4\rho 0.001×100?10000
    WB2.Sheets[1].Range'B3' 'B7').NumberFormat' ← 'dd-mmm-yy'
(...and a bit of formatting, etc.)
    RNG2.Font.Size + 14   RNG.Font.Italic + 1
    RNG2.Interior.Color \leftarrow 256 \perp 0 0 255
    RNG2.Interior.ColorIndex + 44
                                                 A some pre-set colours
    RNG2.ClearFormats
    RNG2.ClearContents
```

Utilities

Rather than invent most of the wheels...

First, find or create an Excel spreadsheet that has more than one worksheet, and some data (numeric or char or a mixture) in a few cells. Then:

```
) LOAD ...\samples\ole\oleauto (in the Dyalog install folder)

DESCRIBE
```

Reading a spreadsheet

Examine XLCONTENTS, (or XLCONTENTS1) and note how control structures are used to navigate through Excel's object hierarchy and collection objects.

Writing To a Spreadsheet

or from APL, you could do these actions separately under program control, as in:

```
(EX.Workbook.Item 1).Close 1

EX.Quit ♦ □EX 'EX'
```

Excel Charts?

```
) ED XLCHART (?? does this work)
```

```
More on Charts?: see David Crossley's XL functions workspace (not trivial), eg. xl_start' '  xl_plot 10120
```

A Few More Tips & Tricks

```
A "activate" a worksheet
XL.Workbooks[1].Sheets[1].Activate
XL.ActiveSheet.UsedRange.Count
XL.ActiveSheet.UsedRange.Address ''
XL.ActiveSheet.UsedRange.Select
                                                   A select a range
Result of Single vs. Multiple Cell Values
(XL.ActiveSheet.Range'C1').Value2
                                                    A depends on cell content (empty?)
(XL.ActiveSheet.Range'C1' 'D1').Value2
Named Ranges (for template-driven output?)
(XL.ActiveSheet.Range'E5' 'H9').Name + 'MyRng1'
(XL.ActiveSheet.Range'MyRng1').Value2 ← mat3
                                                          A populate known ranges
Multi-Area Ranges
(XL.ActiveSheet.Range'C7:D9,F7:G9').Name←'myrng2'
(XL.ActiveSheet.Range'myrng2').Value+(3 2016)(3 20100+16)
                                                                     A ??
(XL.ActiveSheet.Range'myrng2').Value←(3 2016),(3 20100+16)
(XL.ActiveSheet.Range'myrng2').Areas.Count
((XL.ActiveSheet.Range'myrng2').Areas[2]).Value2+99 A scalar extension!
Conclusion: we can only pass a simple (non-enclosed) argument, so one APL array gets split into sub-
arrays according to target-cell geometry in Excel.
```

A Few Other Nifty Things... OLE!

We can launch other OLE applications and/or create documents from APL:

PowerPoint

- find the PowerPoint OLEServer object
- create an OLEClient object which uses the PowerPoint server
- explore the server object properties & methods
- create an APL driver function which will open and run a PowerPoint .pps file

Word

In similar fashion to Excel, we link APL to the OLE Server object for MS-Word, then set or query its various subobjects, etc.

- study the VB code in some of the following: (ie. Google "Word OLE Automation")
 - http://vbcity.com/forums/topic.asp?tid=34572
 - http://groups.google.ca/group/comp.lang.basic.visual.misc/browse_thread/5f469ecaf624045b/a63af721 977b6c7f?lnk=st&q=%27Running+Word+Using+Automation%27+InsertDateTime+MM-DD-YY+HH%3AMM%3ASS&rnum=5&hl=en#a63af721977b6c7f
 - http://support.microsoft.com/?kbid=250501
- emulate this code in APL and create an APL driver function to send arbitrary text to a Word document

OCX Demo

OCX Controls behave similarly to the OLE Server objects above, except they may need to be associated with a Form or other container to be useful. These objects are designed to take on some of the properties of their environment (container).

See: "Loading an ActiveX Control", in the Dyalog Windows Interface Guide (Chapter 11).

• use the 'Microsoft Forms 2.0 TextBox' OLE Control object by building an APL driver function to contain and present this object

PDF

Similar to the OCX control above, Adobe Acrobat provides an ActiveX control which can be used to display a PDF document.

- find the Adobe Acrobat ActiveX component needed to display PDF documents
- create an APL driver function which will display a given PDF document

What Else Is New?

- 1. □WX changes see Session Help "Latest Enhancements": "Expose Windows Object Properties" and "External Object Behaviour"
- 2. **INL** and COM Objects see: Session Help "Latest Enhancements", **INL**, **INC** and "name-class" definitions Extensions for more detailed object information.
- 3. APL Classes based on OLEClient see:

```
240 Dyalog APL/W Interface Guide
```

Writing Classes based on OLEClient

You may define APL Classes (See Language Reference) based upon the OLEClient object. For example:

```
:Class Excel: 'OLEClient'
    v ctor wkbk
     :Access Public
     :Implements Constructor :Base ,c('ClassName' 'Excel.A
pplication!)
     Workbooks.Open <wkbk
:EndClass a Excel
     XL+ | NEW Excel 'f: \help11.0 \days.xls'
     XL.Workbooks[1].Sheets[1].UsedRange.Value2
            To
                Days Hours
  38790
         38791
                        3.25
        38792 [Null]
                        2.25
  38792
  38793
        38793
               [Null]
                        2.5
               [Null]
  38799
        38799
         38800 [Null]
                        3
 38800
 [Null] [Null] [Null]
```

Excel in Control

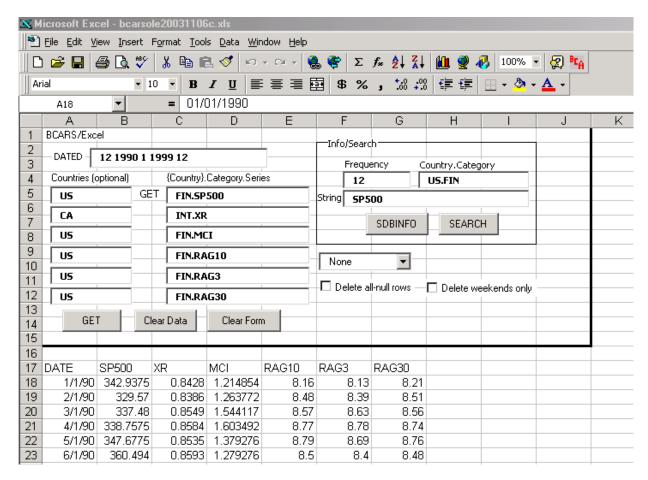

Here, we focus on designing the user interface in Excel/VBA. APL may be "plugged into" this application as a black box, hidden from view normally. APL functions are passed arguments, and return results as with any other Excel/VBA function. Excel is the client, APL the server (often called "calculation server or engine").

In General

Calling APL functions from within your Excel application involves the following steps:

- create appropriate APL code in a workspace, with some special considerations; test and debug
- create/register the required .dll using this code
- create the Excel spreadsheet, including VBA code which links into APL code
- test and debug

In Dyalog APL, we use a Namespace object to contain the code which Excel will call upon, and Dyalog provides a special facility to turn that code into a .dll file.

Dyalog APL provides a built-in facility in the session manager for creating the required .dll object which will deliver APL capability to your Excel application. This is documented in the Dyalog APL "Interface Guide" (Chapter 12: "OLE Automation Server").

Worth reading in that chapter:

- Rules for Exported Functions
- Out-of-Process and In-Process OLE Servers

Key steps include:

- Create an APL workspace containing a namespace, into which all the relevant code and other objects are placed
- make the namespace an OLEServer object, eg. Loan. DWC 'OLEServer'
-) **SAVE** the workspace (use a new name if starting with one of the demos)
- Choose File-Export from the menu, and select "In Process Server (*.dll)" or "Out of Process COM Server" (typically "In Process" - see Dyalog's Interface Guide)

Dyalog APL will automatically package up the namespace contents, "export" those items, and register the supplied Namespace as a .dll object (and produce a small log/report). This .dll is the object we then refer to in our Excel/VBA code, using the CreateObject function.

On the VBA/Excel Side

- Create your spreadsheet typically this will be designed with input areas for data parameters to be passed to APL, and one or more "controls" (buttons, input boxes, etc.)
- Enter "Design Mode", using the toolbar brought into view by: View > Toolbars > Control Toolbox
- Right-click on controls to choose "View Code" or "Properties"; or enter the VBA Macro editor to modify these

Let's look at the supplied example: ...\samples\ole\loan.xls

```
Private Sub CBGet Click()
                                            (or use the "Assign Macro" feature)
         Dim APLWS As Object
         Set APLWS = CreateObject("dyalog.NAMESPACENAME")
Sub Calc()
  Dim APLLoan As Object
  Dim Payments As Variant
  Set APLLoan = CreateObject("dyalog.Loan")
  LoanAmt = Cells(1, 3).Value
  LenMax = Cells(2, 3).Value
  LenMin = Cells(3, 3). Value
  IntrMax = Cells(4, 3).Value
  IntrMin = Cells(5, 3). Value
  APLLoan.PeriodType = 1
  Payments = APLLoan.CalcPayments(LoanAmt, LenMax, LenMin, IntrMax, IntrMin)
  For r = 0 To UBound(Payments, 1)
    For c = 0 To UBound(Payments, 2)
      Cells(r + 1, c + 5).Value = Payments(r, c)
    Next c
  Next r
End Sub
Sub CalcPayments()
                                            (alternate coding to above)
```

The Tricks

For Dyalog APL, the following rules and caveats apply *at creation time*, when creating the .dll through the above process:

- all functions must be niladic or monadic; no dyadic functions, nor dynamic functions, derived functions or operators; this could lead to numerous code changes obviously for some existing systems
- any global variables cannot be enclosed arrays
- results (returned to Excel) may be simple or enclosed
- reporting exceptions, errors, etc. back to Excel can be a chore, depending on desired level of detail

Valence

Make dyadic functions monadic, by combining the arguments into one:

```
R+ CAT1 ARG;A;B;SA;SB

[1] A catenate 2 tables on the 1st axis

[2] A+\BoxIO\supsetARG \diamondsuit B+(\BoxIO+1)\supsetARG

[3] A+(SA+^-2+11,\rho A)\rho A \diamondsuit B+(SB+^-2+11,\rho B)\rho B

[4] R+0,1\downarrowSA[SB \diamondsuit SB+R[SB \diamondsuit SA+R[SA

[5] R+(SA+A),[\BoxIO]SB+B
```

Then, change the syntactic use of each function which has changed, eg.

```
C← CAT1 (A B)
```

Globals

Create "make" functions instead of globals, and invoke these in a "QUADLX" function which is called by VBA before calling any other code, or invoke them as needed at the beginning of other processes or functions, eg.

```
MAKEΔFrequencies
Frequencies+6 2ρCUT'/D/DAILY/W/WEEKLY/M/MONTHLY/Q/QUARTERLY/S/SEMI/Y/YEARLY'
Frequencies+261 52 12 4 2 1,Frequencies
```

Error, Exceptions

Error handling can be as (un)sophisticated as you wish, but consider these suggestions:

- do as much input-checking "up front", ie. in Excel, before sending bad info to APL
- modify your APL code to always return a result, being an error message or valid result; ie. let Excel deal with the result according to content
- return an error code with all results from APL (0 = OK; 1 = not OK, etc.)

A Few Other Issues

1. A hierarchy of Namespaces in your server application?

Chapter 12: OLE Automation Server

263

Implementing an Object Hierarchy

Despite the close correspondence between the object model and Dyalog APL namespace technology, there is one significant difference. OLE does not support object hierarchies in the sense that one object contains or owns another.

20

Instead you must implement object hierarchies using properties that refer to other objects and/or methods that return objects as results.

It is not possible to pass Dyalog APL namespace hierarchies through OLE because OLE does not support them. If you want to write an OLE Automation Server in APL that implements an object hierarchy, you must follow the OLE conventions for doing so.

2. Running your server application on a network?

276 Dyalog APL/W Interface Guide

Configuring an out-of-process OLEServer for DCOM Introduction

When you register an out-of-process OLEServer using File/Export or OLERegister, Dyalog APL automatically updates the Windows registry so that your OLEServer is immediately accessible to an OLE client application running on the same computer.

If you wish to make the same object accessible to client applications running on different computers (using distributed COM, or DCOM) you have to install additional registry entries on the server and on each of the clients.

3. Calling your server asynchronously, see the OLEASYNC workspace, and:

Chapter 12: OLE Automation Server

279

Calling an OLE Function Asynchronously

Introduction

Functions exported by an OLEServer are executed (by the underlying OLE technology) in a synchronous manner. This means that the OLE client must wait for the function to complete before it can continue processing.

In certain cases the client may not be interested in a result from a function and it may be desirable for client not to have to wait. For example, if a function updates files or performs a printing task, it would be nice for the client application to continue while the server performs this task in background, or indeed (using DCOM) on another computer.

4. Writing ActiveX Controls in Dyalog APL - see Interface Guide, Chapter 13

What is an ActiveX Control?

An ActiveX Control is a dynamic link library that represents a particular type of COM object. When an ActiveX Control is loaded by a host application, it runs in-process, i.e. it is part of the host application's address space. Furthermore, an ActiveX Control typically has a window associated with it, which normally appears on the screen and has a user interface.

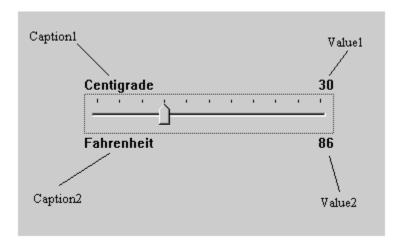

An ActiveX Control is usually stored in file with the extension .OCX. The functionality provided by the control can be supplied entirely by functions in that file alone, or can be provided by other dynamic link libraries that it loads and calls, i.e. an ActiveX Control can be stand-alone or can rely on one or more other dynamic link libraries.

What is a Dyalog APL ActiveX Control?

An ActiveX Control written using Dyalog APL is also a file with a .OCX extension. The file combines a small dynamic link library *stub* and a workspace. The functionality of the control is provided by the functions and variables in the workspace combined with a dynamic link library version of Dyalog APL named DYALOG101.DLL or DYALOG101RT.DLL that is normally installed in the Windows System directory.

Note that an ActiveX Control written in Dyalog APL is a GUI object that has a visible appearance and a user interface.

To write an ActiveX Control in Dyalog APL, you use $\square wc$ to create an ActiveXControl object, as a child of a Form. An ActiveXControl is a container object, akin to a Group or a SubForm, that may contain a whole range of other controls such as Edit, Combo, Button and Grid objects. You may populate your ActiveXControl with other objects at this stage and save them in the workspace. However, you may prefer to create these sub-objects when an instance of the ActiveXControl is created. This happens when your control is loaded by a host application.

ADO and Dyalog APL

Using DAO (precursor to ADO) Dyalog allows us an easy-to-use facility for exploring SQL-based data sources:

With time, one could dive into the SQL function code and create new options for more elaborate selections, update mechanisms, etc.

For databases other than MS-Access and the like, Dyalog offers the ODBC interface tools (Chapter ?? - Interface Guide) which provide a complete and detailed set of utilities for interacting with any of these data sources. This is non-trivial in scope.
